Apply filters to SQL queries

Project description

During the performance of the activities of a cybersecurity specialist, it will be common to use databases to access information that is necessary to know exactly how to proceed. Filtering our searches with conditions that reflect such information is a necessary tool to possess so that the flow of activities is not interrupted by a lack of data on which to make decisions. The following is an example of such activities, illustrating commands, filters, and operators that will be useful when accessing information in a timely and efficient manner, using **SQL**.

Retrieve after hours failed login attempts

The normal working hours in the organization end at 18:00:00, so to detect anomalous patterns, we looked for login attempts after that time. In addition, we included the condition that these attempts had failed (reflected in the 'success' column with a '0'). To do this, we use the **'where'** command to include the first condition and the logical filter **'and'**, as seen below:

```
MariaDB [organization]> select * from log_in_attempts where login_time > '18:00:00' and success = 0;
+----------+----------+------------+------------+---------+-----------------+---------+
| event_id | username | login_date | login_time | country | ip_address      | success |
+----------+----------+------------+------------+---------+-----------------+---------+

```

Retrieve login attempts on specific dates

To review a suspicious event that occurred on 2022-05-09, we need to analyze the login attempts on that date and also during the previous day, 2022-05-08. Again we use the "**where**"

command to indicate the first condition, and in this case, we use the logical "**or**" filter. In this way, we are asking the database to return the relevant information that meets the first or second condition.

```
MariaDB [organization]> select * from log_in_attempts
    -> where login_date = '2022-05-08'
    -> or login_date = '2022-05-09';
+----------+----------+------------+------------+---------+-----------------+---------+
| event_id | username | login_date | login_time | country | ip_address      | success |

```

Retrieve login attempts outside of Mexico

Since it is known that during the suspicious event, there were no login attempts from Mexico, we need the information that does not contain "MEX" or "MEXICO", so we use the logical filter "**not**". Also, since the format in which the country names are written is not consistent throughout the table, we use the "**like**" operator to tell the database to return the values that contain the character string specified as a condition. In this case, the condition includes the symbol "**%**" which is a wildcard representing any number of characters. In this way, we ensure that both rows containing "MEX" and rows containing "MEXICO" will be returned by the database.

```
MariaDB [organization]> select * from log_in_attempts where not country like 'MEX%';
+----------+----------+------------+------------+---------+----------------+---------+
| event_id | username | login_date | login_time | country | ip_address     | success |
+----------+----------+------------+------------+---------+----------------+---------+

Retrieve employees in Marketing

The security team needs to update the computers of the people in the Marketing department, specifically in the East building of the organization. Again we use "**where**" to specify the name of the department and similar to the previous activity, the "**like**" operator is used to tell the database to return rows containing "East", using the wildcard "**%**".

```
MariaDB [organization]> select * from employees
    -> where department = 'Marketing'
    -> and office like 'East%';
+-------------+--------------+----------+------------+----------+
| employee_id | device_id    | username | department | office   |
+-------------+--------------+----------+------------+----------+
|        1000 | a320b137c219 | elarson  | Marketing  | East-170 |

+-------------+--------------+----------+------------+----------+
7 rows in set (0.001 sec)
```

Retrieve employees in Finance or Sales

The computers of the people in the sales and finance department also need a different update, so we need all the relevant information from both. For this we use "**or**", as the database will return the values if one condition is met, or the other, or both.

```
MariaDB [organization]> select * from employees
    -> where department = 'Sales'
    -> or department = 'Finance';
+-------------+--------------+----------+------------+-------------+
| employee_id | device_id    | username | department | office      |

|        1035 | j236k3031245 | bisles   | Sales      | South-171   |
```

Retrieve all employees not in IT

Finally, one more update is required. In this case, the computers of the people working in the 'Information Technology' department already have the most current version and do not need any more patches, for now. As all relevant information not related to this department is needed, we use the logical filter "**not**" which, as expected, negates the condition. That is, we are asking the database to display information from all departments except IT.

```
MariaDB [organization]> select * from employees
    -> where not department = 'Information Technology';
+-------------+-------------+----------+-----------------+-------------+
| employee_id | device_id   | username | department      | office      |

Summary

Being fast and accurate when extracting information from a database is critical to maintaining a correct flow of an organization's activities, specifically those that have to do with events that represent risks to the integrity and confidentiality of the information.
